Precipitation Prediction by ARPS

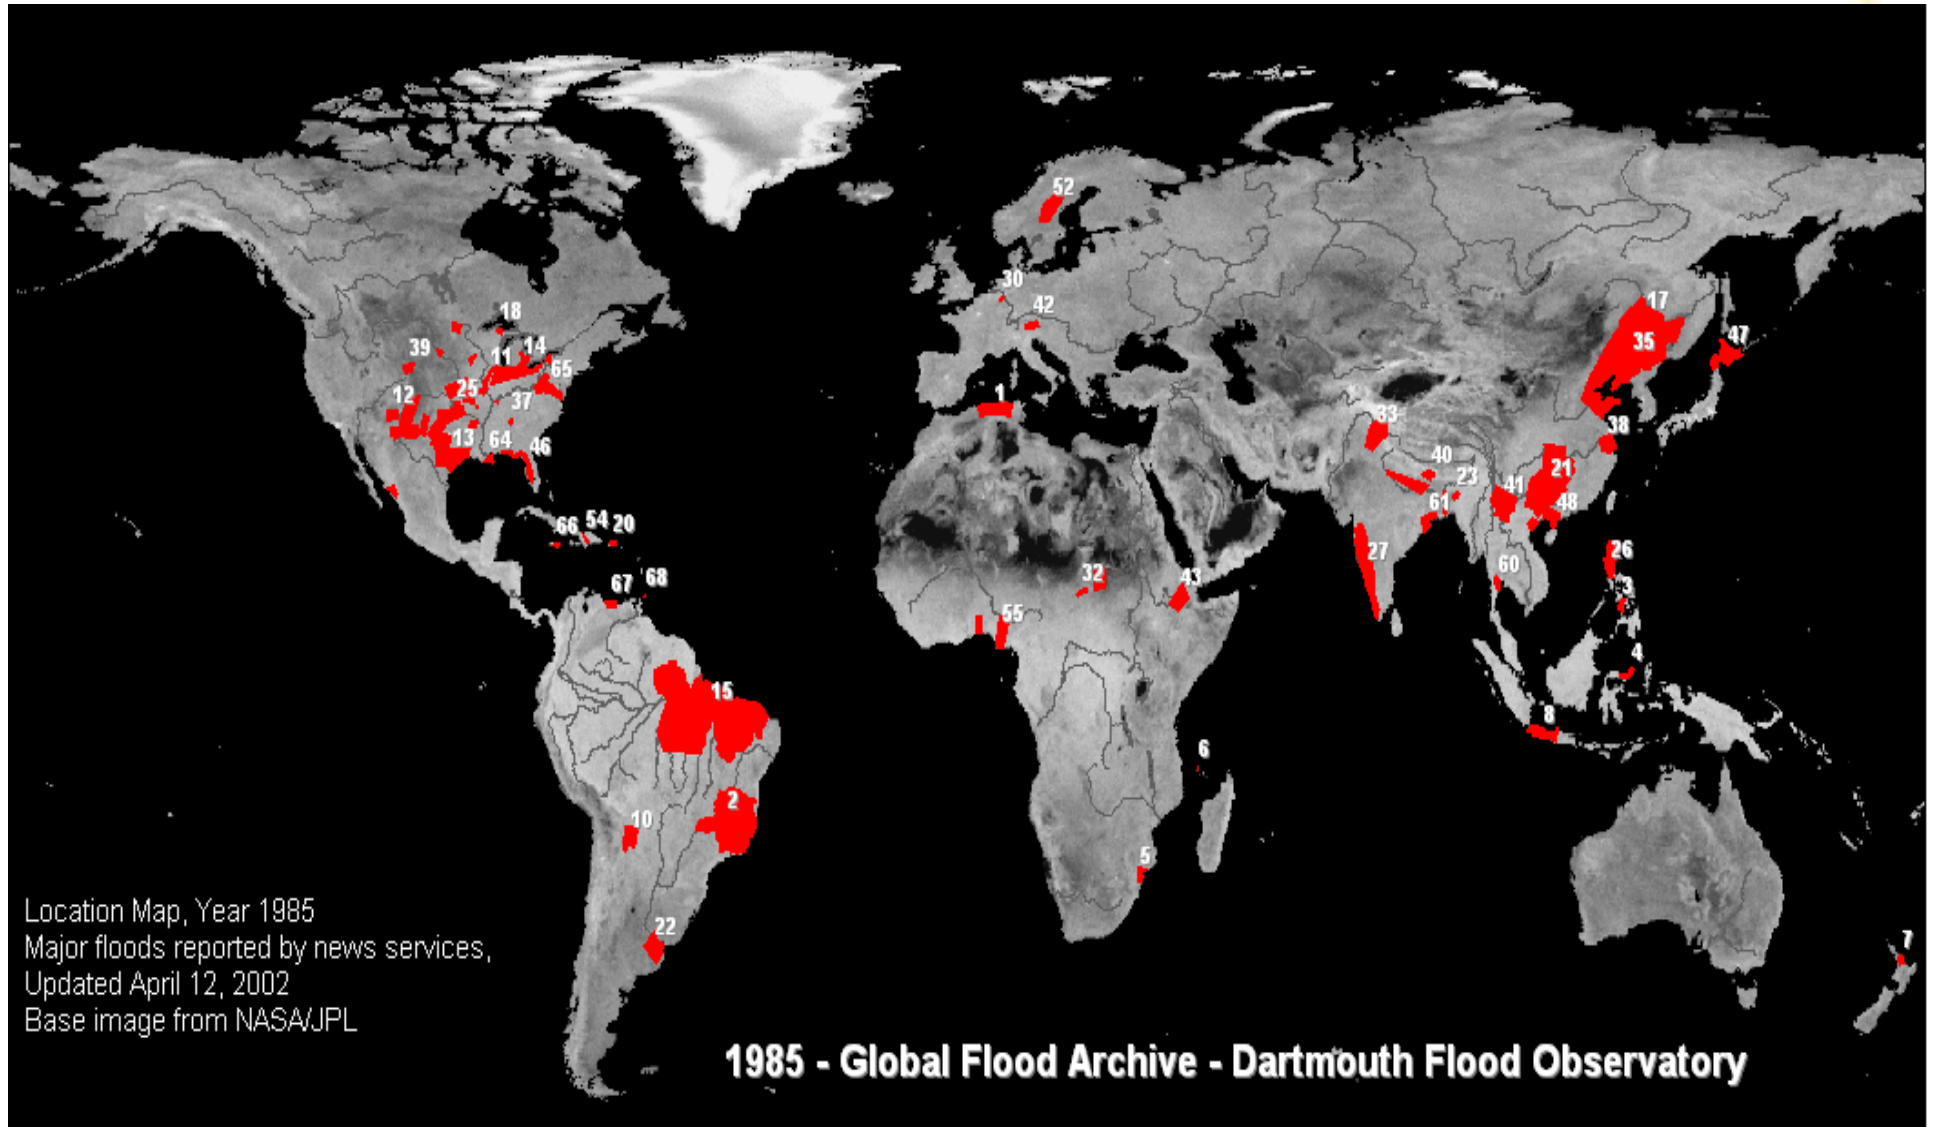

Conclusions

● Frequency of Torrential Rainfall and flooding

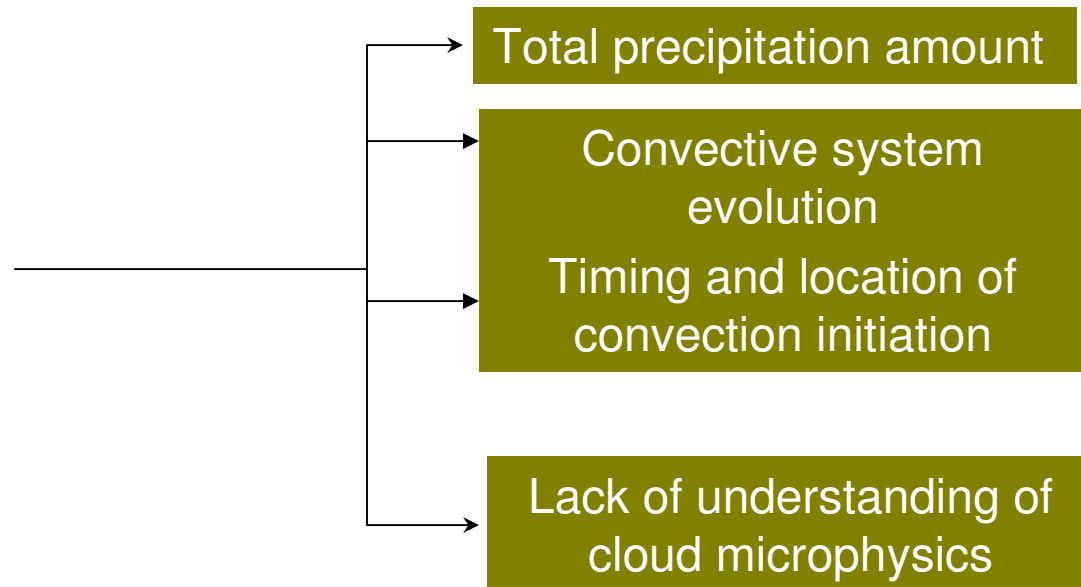

Problem Statements

- Convective storms → many sizes, produce hazardous weather events. Various isolated storms organized → Larger clusters of storms → Mesoscale Convective Systems (MCSs).
- Due to problems with initial conditions and convective parameterization schemes, most operational models are unreliable for predicting MCSs.

- Most NWP Models have difficulty for Pcep. predicting:

How can a forecaster use NWP to predict MCSs?

- Higher resolution
- Look for favorable synoptic and mesoscale patterns in NWP products
- Look for predicted buoyancy
- Be alert for synoptic positioning/timing errors and any known model biases
- Watch for predictions of unrealistic looking precipitation “bull's-eyes” due to convective parameterization limitations

- But in spite of all that intellectual precautions, Precipitation → most difficult forecast parameter → in NWP. Improvements in numerical modeling → Reduction in forecast errors → Winds, temperature, sea level pressures and geo-potential heights → But progress in precipitation prediction → bit slow.

Short range Precipitation
Prediction

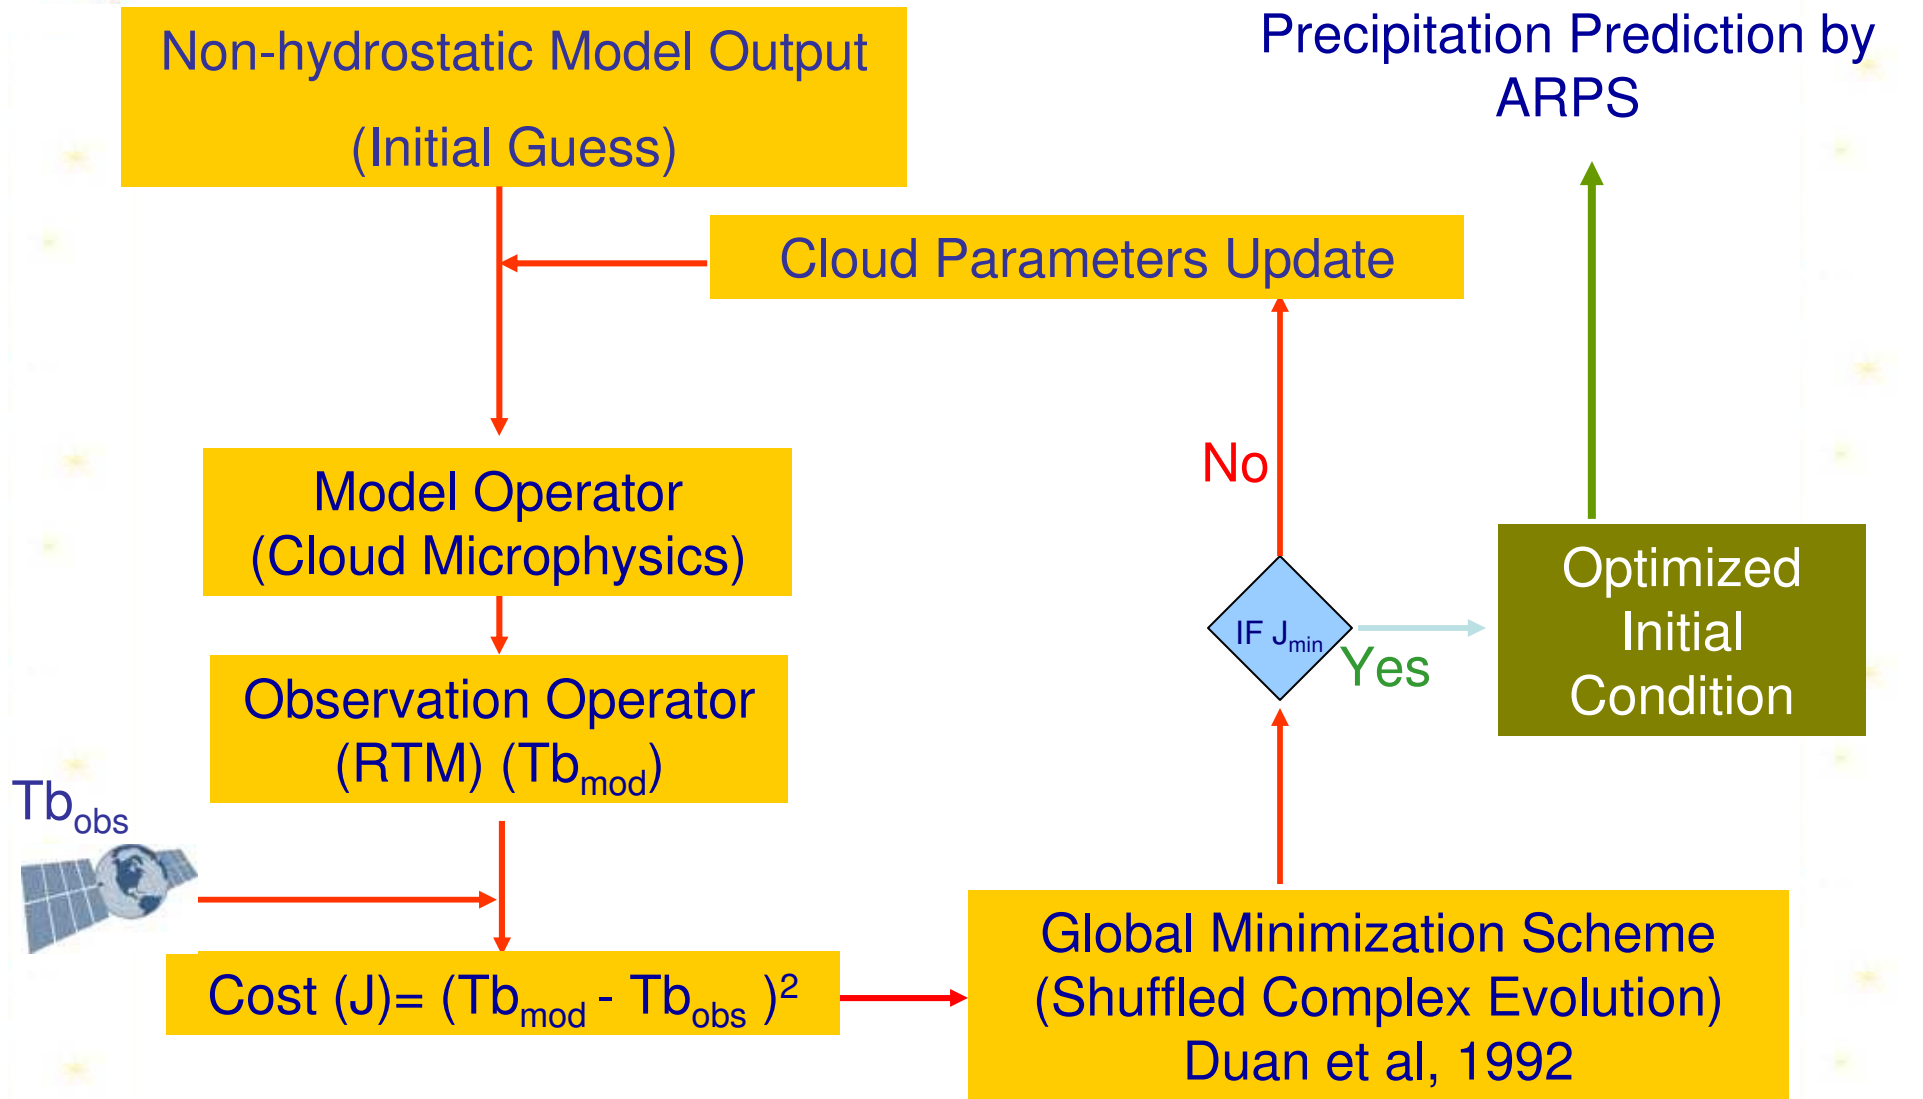

Motivations

- Output of NWP → Use as a initial step but can't rely on the prediction results of rainfall and CLWC. Therefore, by combining the model output and satellite observations, more reliable CLWC information & precipitation prediction can be made.
- By using GDAS output as IC of the mesoscale model & Satellite data, IC → finer grid scale model → more reliable precipitation prediction for local area → Ultimately contribute to unguaged basins.
- By having better precipitation prediction, we can safe the human lives by having confidence on flood forecasting and river water managements.

CMDAS Methodology

Theoretical distributions of assimilated Variables

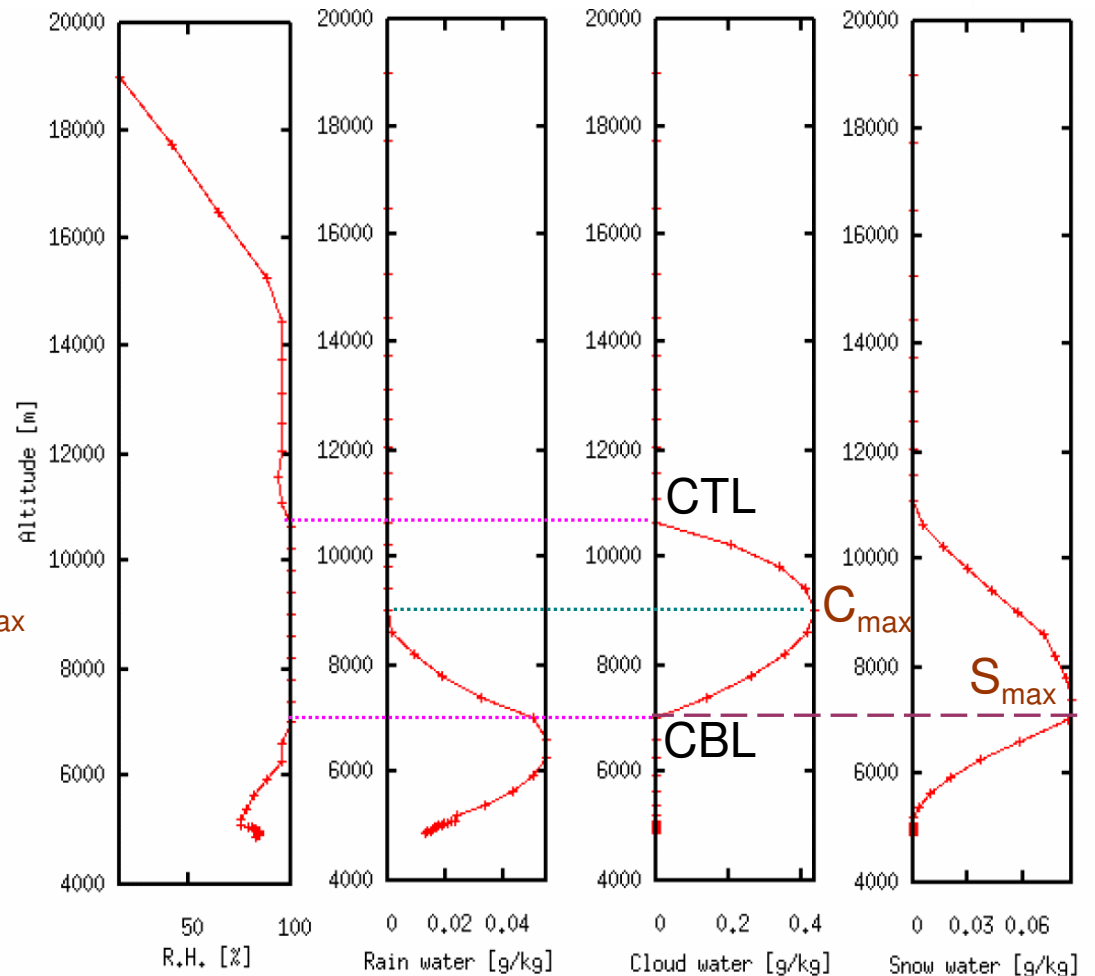

Assumptions:

IWV: Air_{sat} i.e R.H = 100% [cloud Region]

ICLWC: Parabolic Distribution with Max. CLWC at center of cloud .

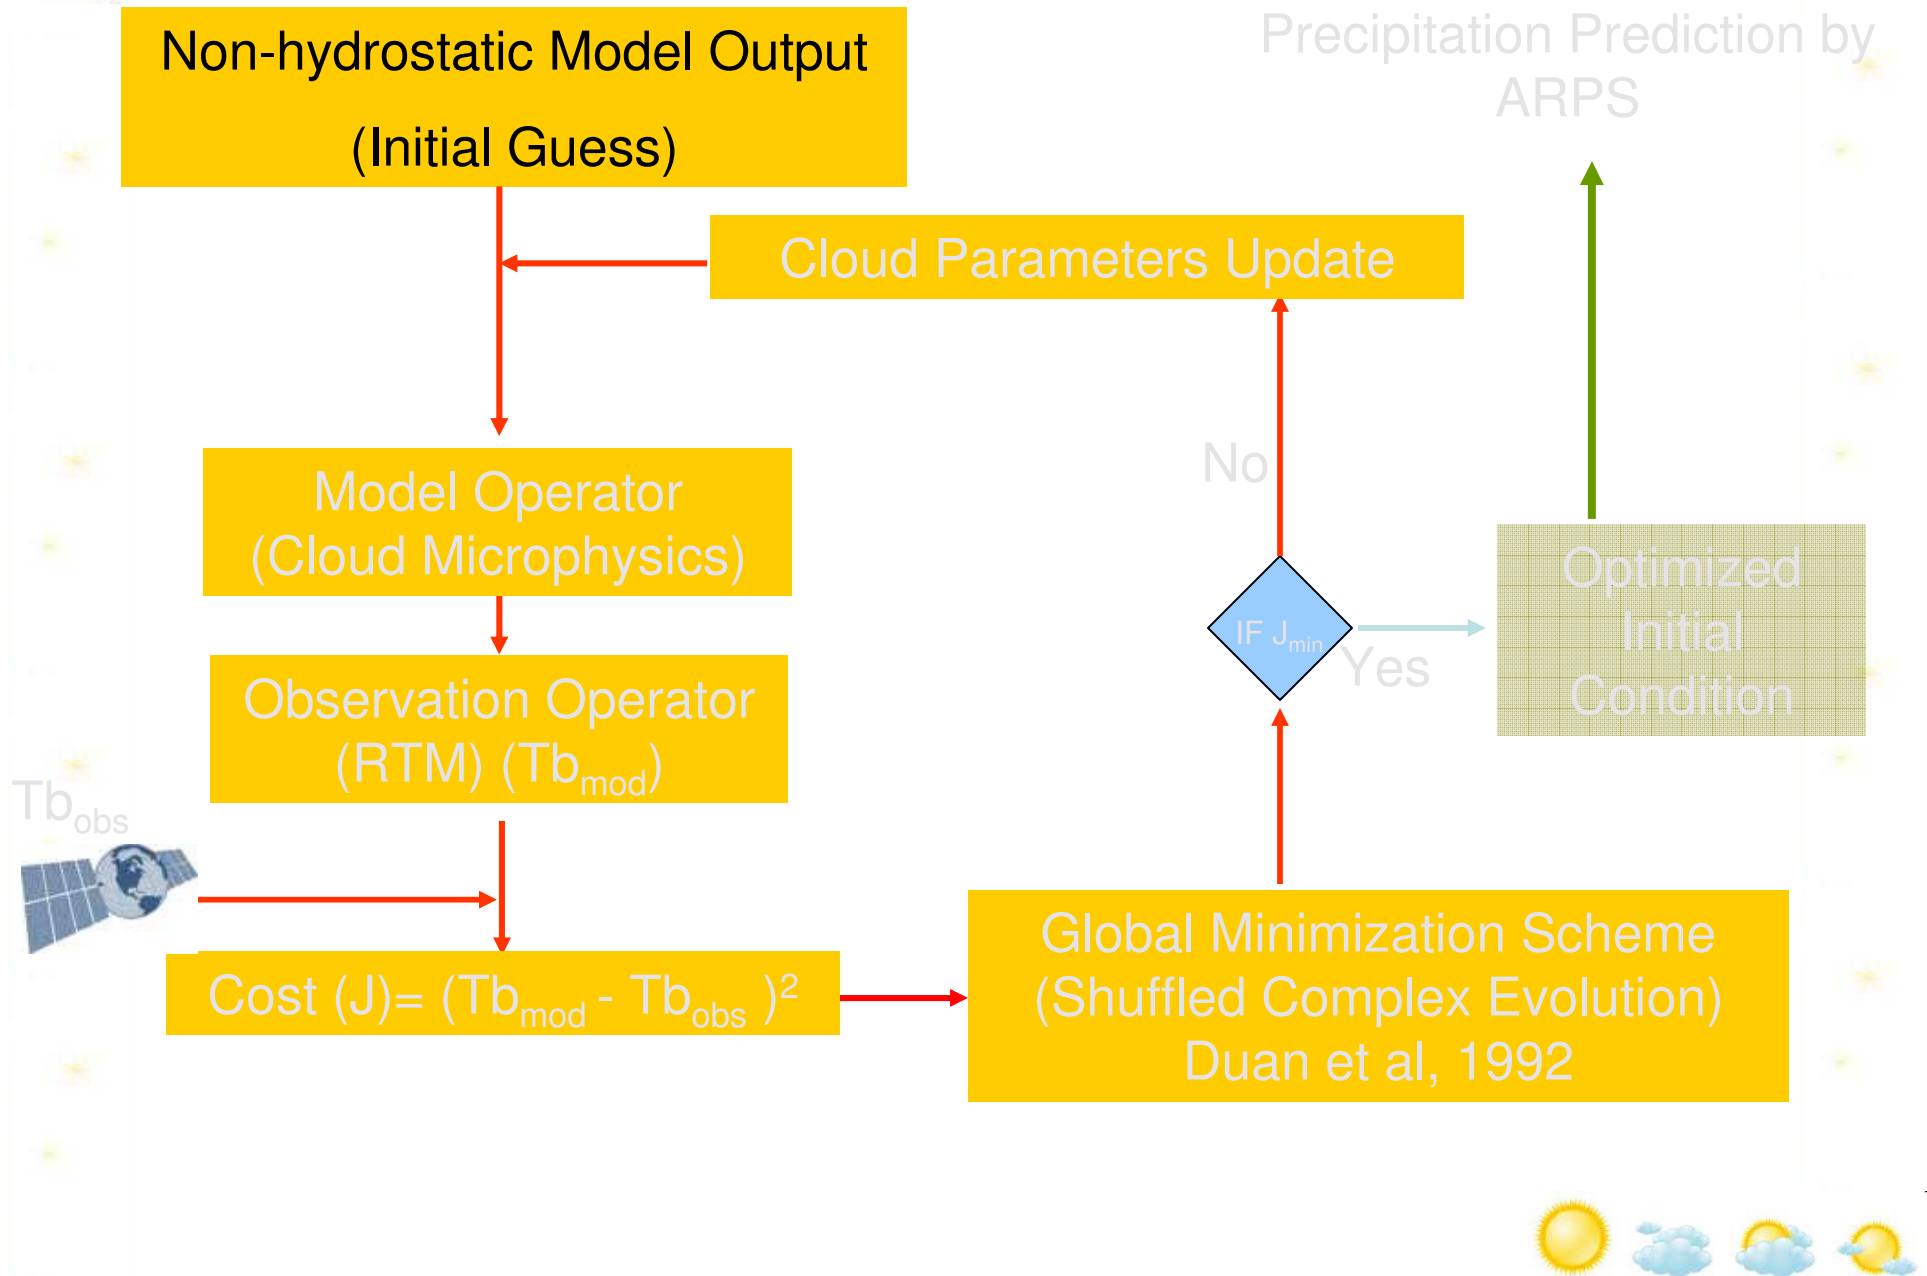

IRW : Skewed profile of ICLWC, rain drops formation start from C_{max}

ISW : Snow formation starts from CT reaching to S_{max} at CBL.

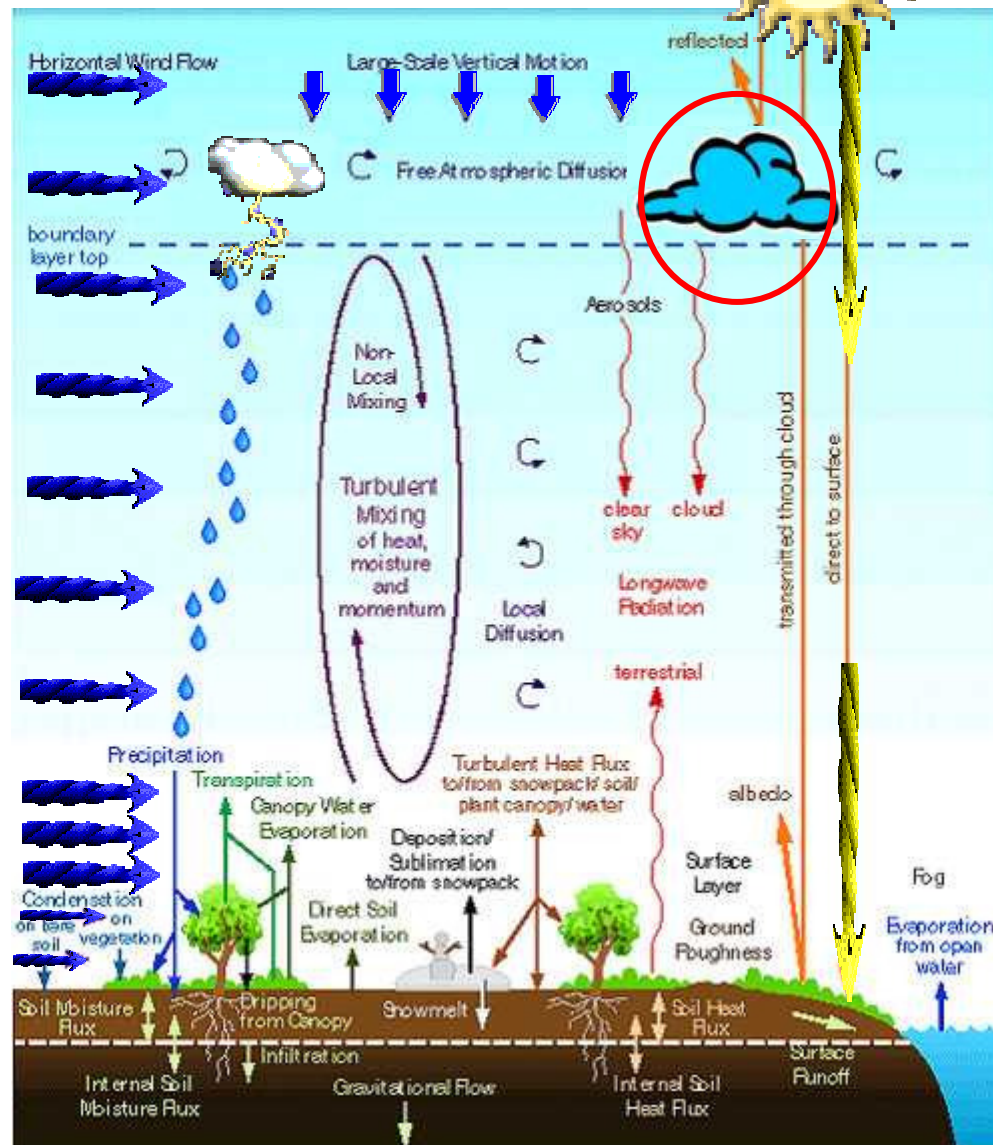

Cloud Microphysics Data Assimilation System (CMDAS) Methodology

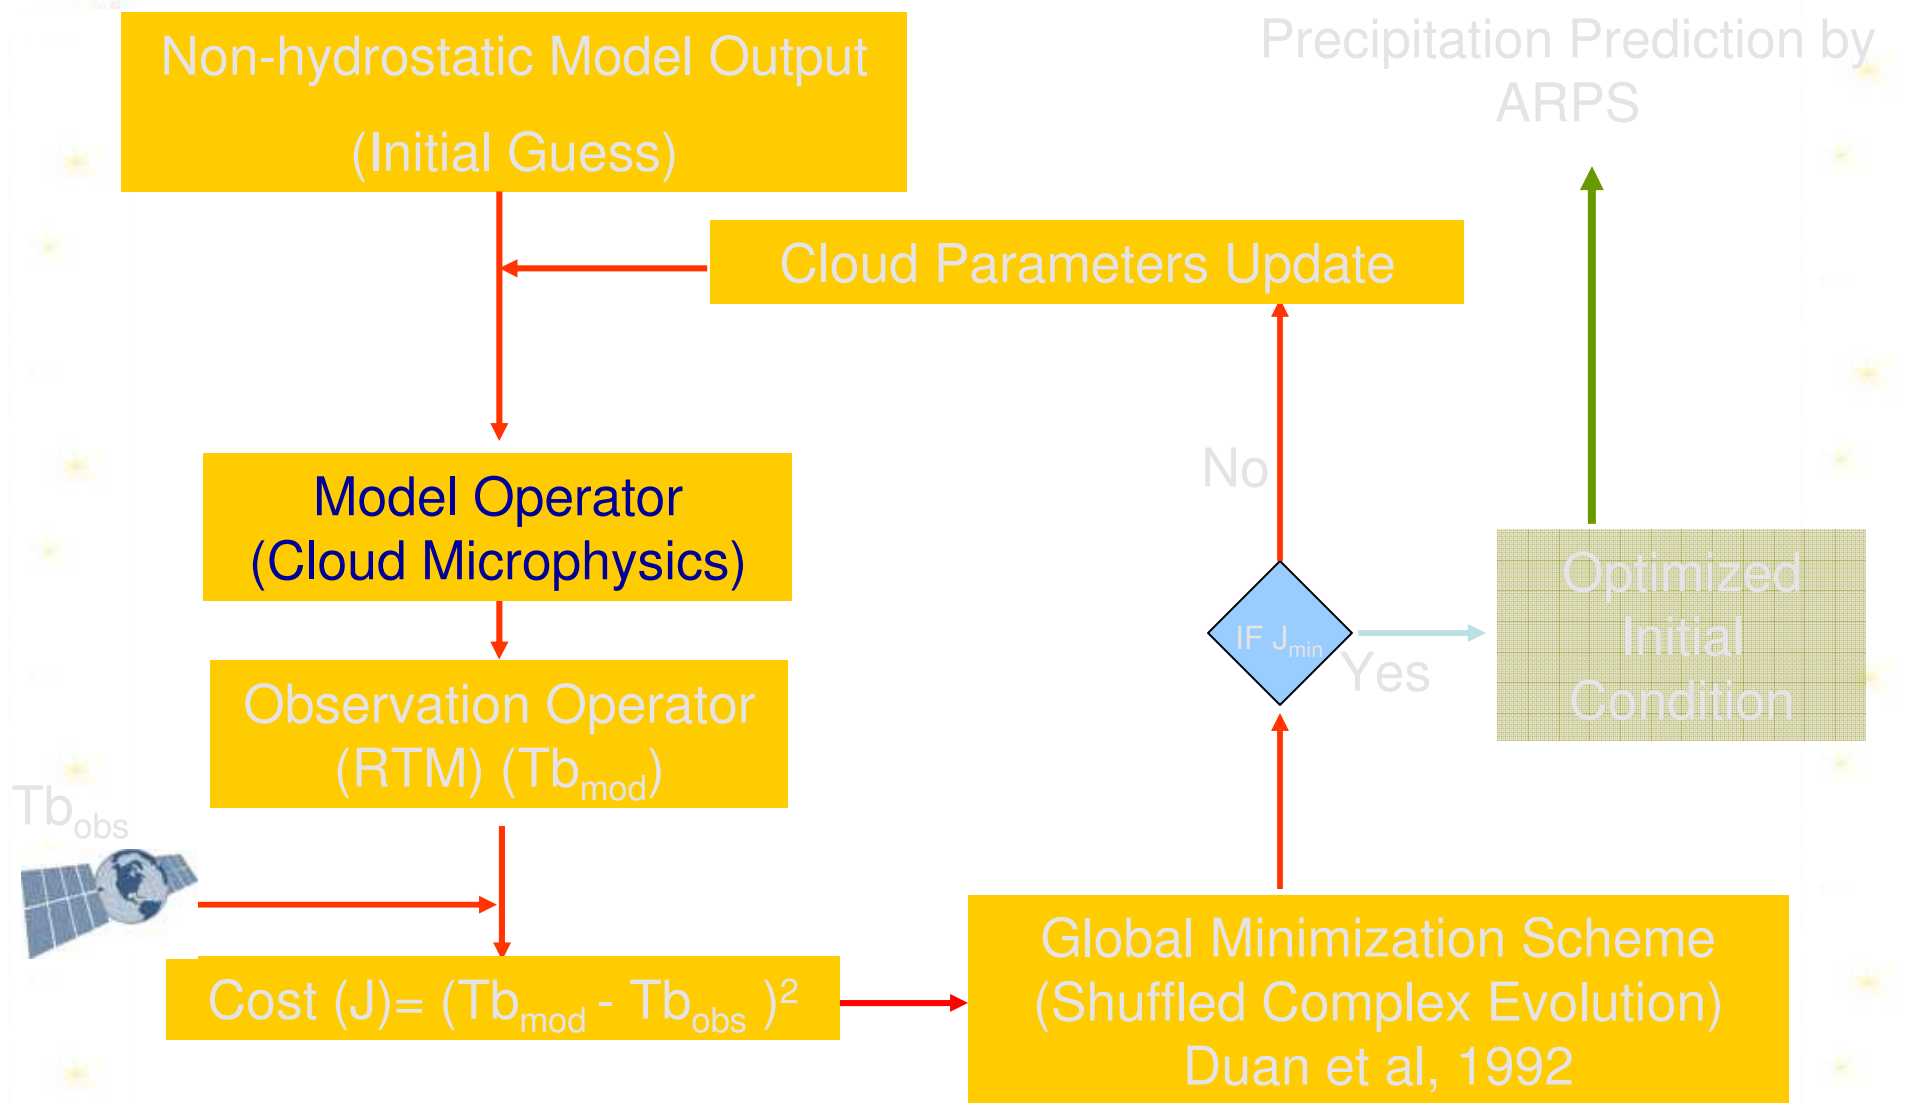

Numerical Model Physics: ARPS

CMDAS Methodology

Cloud Microphysics

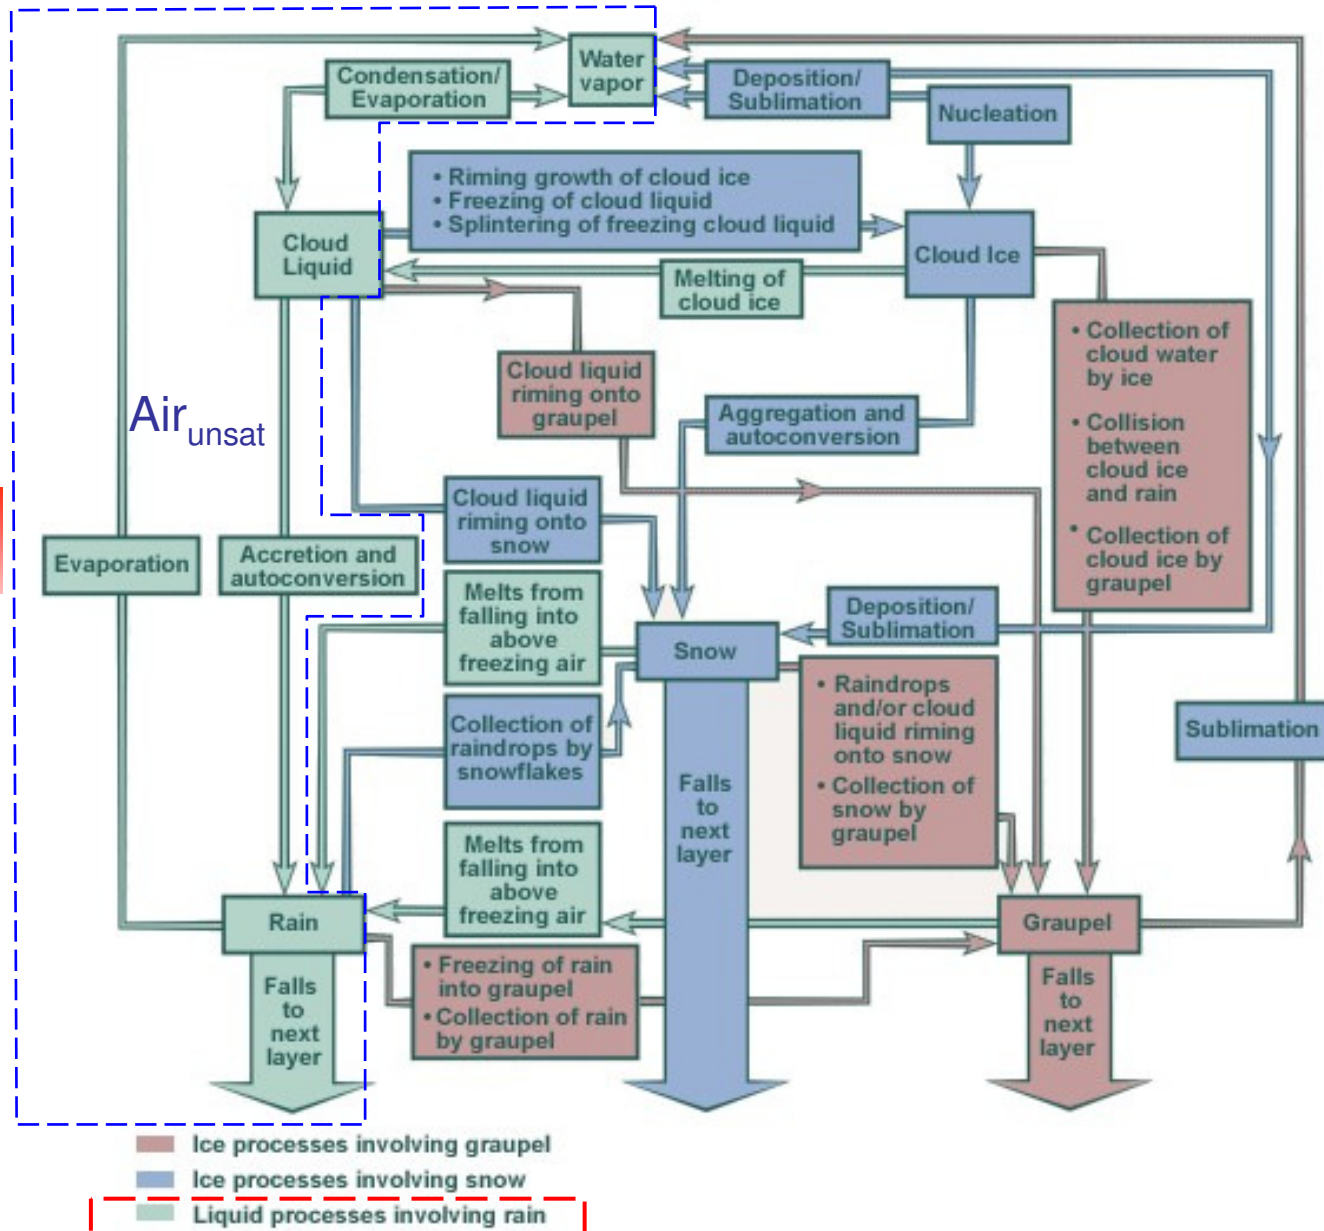

- Clouds form due to cooling of large parcels of air to a temperature below their dew point. These large scale processes are referred as “Cloud Dynamics”.
- Cloud droplets usually form & evolve to form precipitation due to much smaller scale processes occurring on the order of particle size → “Cloud Microphysics”.

Precipitation Prediction by ARPS

Conclusions

Niigata Extreme Event

In 12th July 2004, a Baiu-front from the Japan Sea to the Niigata area was activated by warm and moist air blowing from the South caused by Record breaking number of typhoons without losing their force over Japan.

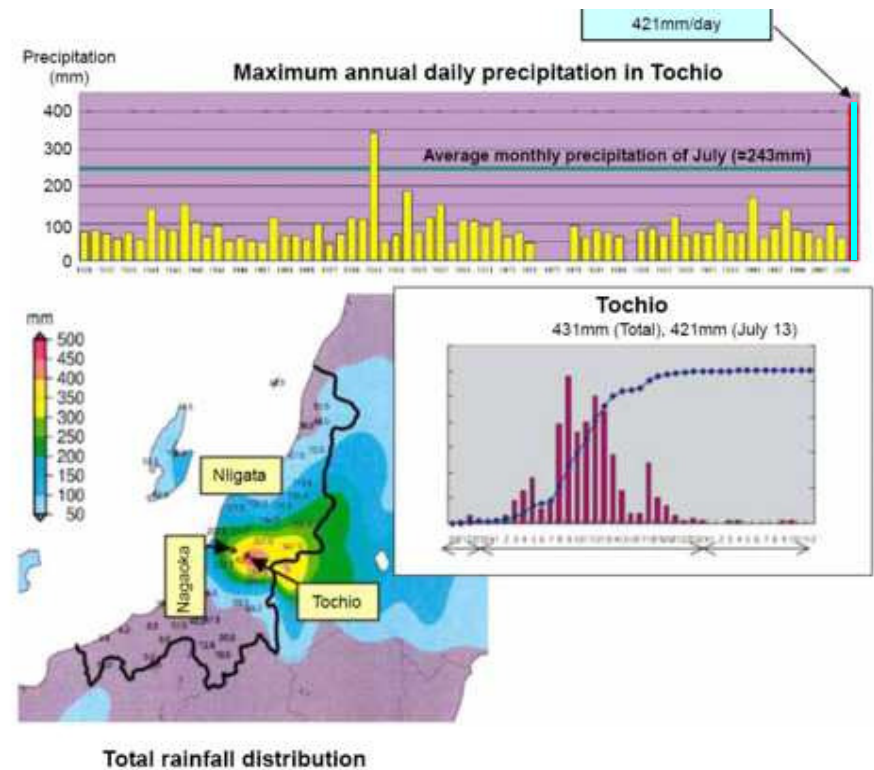

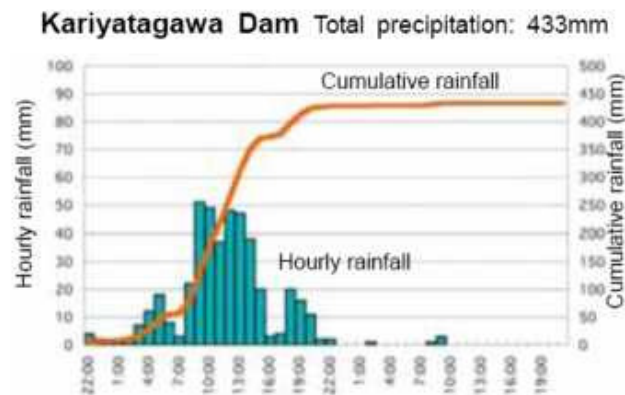

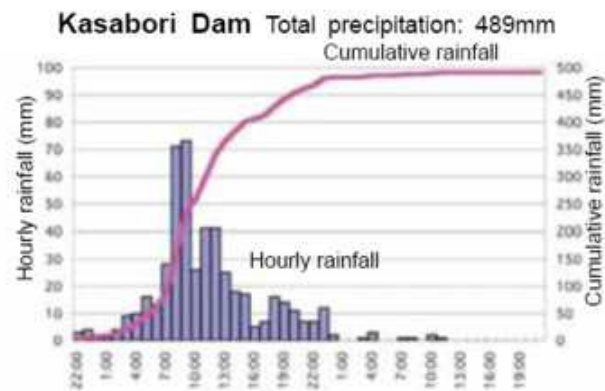

Niigata Extreme Event.....

Daily Torrential precipitation of 13 July reached 421 mm in Tochio City, nearly twice the average monthly precipitation of July in Tochio (243 mm).

Historical Regional heavy rainfall

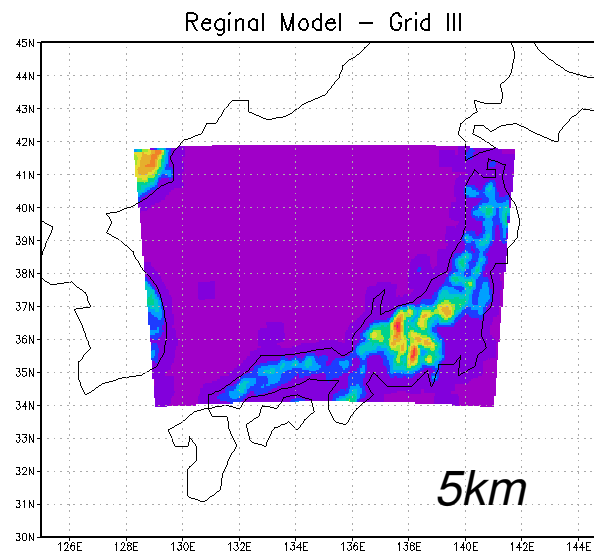

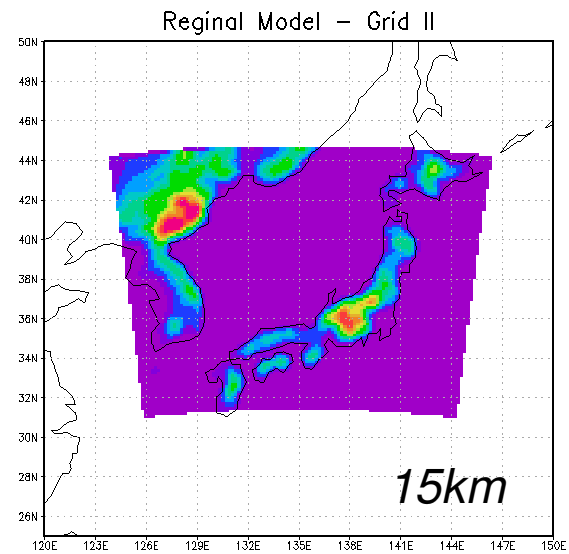

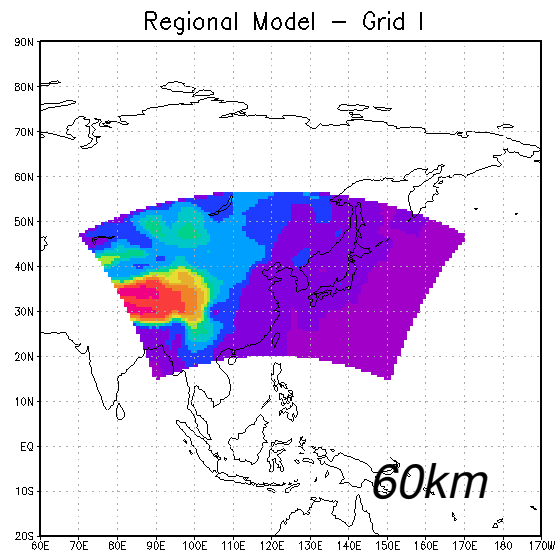

Experimental Design of Niigata Flood (ARPS)

Event	Niigata Heavy Rainfall (12 th July ~ 13 th July 2004)
domain	600 km × 600 km × 20km
horizontal grid size	5000 m
vertical grid size	5000 m
Resolution	60, 15, 5 Sq. Km
integration time	48 hrs
time increment	10 sec for model integration
Initial/Boundary condition	GFS (Global Forecast System) analysis (1x1)
Cloud microphysics	Lin Ice scheme
CPS	Kain-Fritch

Vietnam Extreme Event

- Band of topographically-forced convective clouds occurred north of 15°N in the Truong Son Mountains → Propagated northward off the mountains towards the coast
- From 24 to 26 November 2004 an extreme heavy rainfall event occurred in the mountainous provinces of central Vietnam, resulting in flooding along local rivers and severe human and property damage.

Conclusive Remarks

Dynamical downscaling could be able to improve the short term precipitation prediction by improving BCs which come from GCMs

Assimilated brightness temp. and integrated parameters show good agreement with observation

Forecasting with improved initial conditions shows agreement in the beginning, however the generated cloud system by CMDAS seems dying later on.

→ Cloud dynamics play important role to keep the energy to develop the cloud system further more.

Unable to predict the Niigata heavy rainfall event, even with dynamical downscaling → due to NCEP reanalysis data → Need better BC data

Precipitation rate Analysis: For initial 6 hrs, ARPS with new IC from CMDAS gives comparable precipitation spatial and temporal distribution with AMeDAS radar rain rate values (Niigata Extreme Event case).

The spatial and temporal distribution & over/under-estimation displacement of precipitation over Vietnam area by ARPS → maybe due to uncertain/lack of low level convergence to support the continued growth of the initial and split updraft.

**Thanks for your efforts by
facilitating us with better water
resources management !!**
